

production and flocculation of *Chaetoceros* as the main ingredient, and a 100 ha fenced grow out area which is trapped continuously to remove benthic predators.

- Growth and survival rates have varied widely between animals planted in similar habitats. The pre-plant health and stocking density seem to have the greatest affect on future growth and survival of juvenile conch.
- Continued work on algal food requirements and on grow out pastures and techniques are needed, as these are the remaining constraints to profitability.
